Guide ID: TS-01-PRN-410

Revision: Rev 1.0

Owner: Service Desk and Site Support

Use Case: Frontline diagnosis before depot repair or infrastructure escalation

Review Cycle: Every 6 months or after repeat incidents

OVERVIEW

This guide helps frontline support and line leads diagnose label print drift, skew, and horizontal offset on the fictional PRN-410 thermal label printer used at packing lanes. It assumes the printer powers on and feeds media, but the printed image does not align consistently with the label stock.

COMMON SYMPTOMS

- Printed barcodes drift toward the leading or trailing edge after several labels.
- The first label after calibration looks correct, but the next ten labels walk out of position.
- Left margin is acceptable on narrow labels but clipped on wide labels loaded from the same roll family.
- Operators report frequent media-out or gap-sensor prompts after roll changes.

LIKELY CAUSES

- Improper media sensor position after a roll change.
- Print-head pressure imbalance or partially latched print-head assembly.
- Incorrect label size, gap, or top-of-form setting in the workstation profile.
- Contamination on the platen roller causing the stock to drift under tension.

DIAGNOSTIC WORKFLOW

- Confirm the exact label part number and compare it with the workstation profile currently assigned to the lane.
- Inspect media path alignment marks and verify the movable guide lightly touches the stock without bowing it.
- Clean the platen roller and sensor window, then print five blank feeds followed by a calibration page.
- Print a ten-label test batch and note whether drift begins immediately or only after the printer warms up.
- If the issue appears only on one workstation, compare page setup and printer preference values with a known-good lane using the same label size.

RECOVERY ACTIONS

- Reseat the roll, reposition the media guide, and rerun calibration if the stock is visibly off center.
- If software settings are wrong, correct label width, height, and top-of-form values, then print a fresh ten-label batch.
- If drift persists after cleaning and settings validation, replace the platen roller and retest before escalating.
- If a print-head latch is not closing evenly, remove the printer from service and swap in the spare lane device.

ESCALATION CRITERIA

- Escalate after two failed recalibration attempts on the same stock.
- Escalate immediately if the print head cannot latch evenly or if labels wrinkle under the print head.
- Attach one successful sample label and one failed sample label to the service ticket if the issue is intermittent.

FIELD NOTES

A useful question for later RAG testing is whether the guide tells the operator to compare workstation settings with a known-good lane before replacing parts. It does, and that detail matters because many alignment issues are profile-related rather than hardware-related.

Another realistic variation is drift that appears only after warm-up. That hints at mechanical friction or roller condition instead of a simple gap-sensor position problem.

APPENDIX 1: REFERENCE NOTES

This appendix page extends the fictional source material with supporting examples, logging expectations, and exception notes so later retrieval tests can traverse a longer document without relying on private or derived content.

Examples on appendix pages are intentionally consistent with the body of the document. They repeat the same operating vocabulary but add different details such as timings, thresholds, role ownership, and escalation triggers.

- Record location code, equipment identifier, shift, and operator initials on each manual intervention.
- If a procedure references a tolerance band, use the tolerance from the most recent approved revision rather than memory or verbal guidance.
- If a required part is unavailable, tag the task as deferred and note the risk to continued operation in the maintenance or service log.
- For training simulations, supervisors may role-play escalation decisions, but the written record should still reflect the documented path in this guide.
